</table>
Once you have persisted objects you need to query them. For example if you have a web application representing an online store, the user asks to see all products of a particular type, ordered by the price. This requires you to query the datastore for these products. Jakarta Persistence specifies support for

- **JPQL**: a string-based query language between SQL and OO.
- **Criteria**: following JPQL syntax but providing an API supporting refactoring of classes and the queries they are used in.
- **Native**: equates to SQL when using RDBMS, and CQL when using Cassandra.
- **Stored Procedures**: in-datastore invocation of stored procedures for RDBMS datastores.

Which query language is used is down to the developer. The data-tier of an application could be written by a primarily Java developer, who would typically think in an object-oriented way and so would likely prefer **JPQL**. On the other hand the data-tier could be written by a datastore developer who is more familiar with SQL concepts and so could easily make more use of **SQL**. This is the power of an implementation like DataNucleus in that it provides the flexibility for different people to develop the data-tier utilising their own skills to the full without having to learn totally new concepts.

There are 2 categories of queries with Jakarta Persistence :-

- **Programmatic Query** where the query is defined using the Jakarta Query API.
- **Named Query** where the query is defined in MetaData and referred to by its name at runtime (for **JPQL**, **Native Query** and **Stored Procedures**).
Query API

Let's now try to understand the Query API in Jakarta. We firstly need to look at a typical Query. We'll take 2 examples

Let's create a JPQL query to highlight its usage

```java
Query q = em.createQuery("SELECT p FROM Product p WHERE p.param2 < :threshold ORDER BY p.param1 ASC");
q.setParameter("threshold", my_threshold);
List results = q.getResultList();
```

In this Query, we implicitly select JPQL by using the method `EntityManager.createQuery()`, and the query is specified to return all objects of type `Product` (or subclasses) which have the field `param2` less than some threshold value ordering the results by the value of field `param1`. We've specified the query like this because we want to pass the threshold value in as a parameter (so maybe running it once with one value, and once with a different value). We then set the parameter value of our `threshold` parameter. The Query is then executed to return a List of results. The example is to highlight the typical methods specified for a (JPQL) Query.

And for a second example we create a native (SQL) query

```java
Query q = em.createNativeQuery("SELECT * FROM Product p WHERE p.param2 < ?1");
q.setParameter(1, my_threshold);
List results = q.getResultList();
```

So we implicitly select SQL by using the method `EntityManager.createNativeQuery()`, and the query is specified like in the JPQL case to return all instances of type `Product` (using the table name in this SQL query) where the column `param2` is less than some threshold value.

**setFirstResult(), setMaxResults()**

A query will by default return all of the results that it finds. You can restrict how many results are returned by use of two methods. So you could do

```java
Query q = em.createQuery("SELECT p FROM Product p WHERE p.param2 < :threshold ORDER BY p.param1 ASC");
q.setFirstResult(1);
q.setMaxResults(3);
```

so we will get results 1, 2, and 3 returned only. The first result starts at 0 by default.

**setHint()**

Jakarta's query API allows implementations to support extensions ("hints") and provides a simple
For enabling the use of such extensions on queries:

```java
q.setHint("{extension_name}", value);
```

Jakarta Persistence supports some standard hints, namely `jakarta.persistence.fetchgraph`, `jakarta.persistence.loadgraph`, `jakarta.persistence.query.timeout`, `jakarta.persistence.lock.timeout`. DataNucleus provides various vendor-specific hints for different types of queries (see different parts of this documentation).

**setParameter()**

When queries take values (literals) it is usually best practice to define these as parameters. Jakarta’s query API supports named and numbered parameters and provides method for setting the value of particular parameters. To set a named parameter, for example, you could do

```java
Query q = em.createQuery("SELECT p FROM Product p WHERE p.param2 < :threshold ORDER BY p.param1 ASC");
q.setParameter("threshold", value);
```

To set a numbered parameter you could do

```java
Query q = em.createQuery("SELECT p FROM Product p WHERE p.param2 < ?1 ORDER BY p.param1 ASC");
q.setParameter(1, value);
```

Numbered parameters are numbered from 1.

**getResultList()**

To execute a Jakarta query you would typically call `getResultList`. This will return a List of results. This should not be called when the query is an "UPDATE"/"DELETE".

```java
Query q = em.createQuery("SELECT p FROM Product p WHERE p.param2 < :threshold ORDER BY p.param1 ASC");
q.setParameter("threshold", value);
List results = q.getResultList();
```

**getSingleResult()**

To execute a Jakarta query where you are expecting a single value to be returned you would call `getSingleResult`. This will return the single Object. If the query returns more than one result then you will get a `NonUniqueResultException`. This should not be called when the query is an "UPDATE"/"DELETE".
executeUpdate()

To execute a Jakarta UPDATE/DELETE query you would call `executeUpdate`. This will return the number of objects changed by the call. This should not be called when the query is a "SELECT".

```java
Query q = em.createQuery("SELECT p FROM Product p WHERE p.param2 = :value");
q.setParameter("value", val1);
Product prod = q.getSingleResult();
```

setQueryMode()

By default, when a query is executed it will be evaluated against the contents of the datastore at the point of execution. If there are any outstanding changes waiting to be flushed then these will not feature in the results. To make sure all outstanding changes are respected

```java
q.setFlushMode(FlushModeType.AUTO);
```

setLockMode()

Jakarta Persistence allows control over whether objects found by a fetch (JPQL query) are locked during that transaction so that other transactions can’t update them in the meantime. For example

```java
q.setLockMode(LockModeType.PESSIMISTIC_READ);
```

You can also specify this for all queries for all EntityManagers using a persistence property `datanucleus.rdbms.useUpdateLock`.

Large Result Sets : Loading Results at Commit()

When a transaction is committed by default all remaining results for a query are loaded so that the query is usable thereafter. With a large result set you clearly don’t want this to happen. So in this case you should set the query hint `datanucleus.query.loadResultsAtCommit` to `false`, like this

```java
query.setHint("datanucleus.query.loadResultsAtCommit", "false");
```
Result Set : Caching of Results

When you execute a query, the query results are typically loaded when the user accesses each row. Results that have been read can then be cached locally. You can control this caching to optimise it for your memory requirements. You can set the query hint `datanucleus.query.resultCacheType` and it has the following possible values:

- **weak**: use a weak reference map for caching (default)
- **soft**: use a soft reference map for caching
- **strong**: use a Map for caching (objects not garbage collected)
- **none**: no caching (hence uses least memory)

To do this on a per query basis, you would do

```java
query.setHint("datanucleus.query.resultCacheType", "weak");
```

Large Result Sets : Size

If you have a large result set you clearly don't want to instantiate all objects since this would hit the memory footprint of your application. To get the number of results many JDBC drivers, for example, will load all rows of the result set. This is to be avoided so DataNucleus provides control over the mechanism for getting the size of results. The persistence property `datanucleus.query.resultSizeMethod` has a default of `last` (which means navigate to the last object, hence hitting the JDBC driver problem). On RDBMS, if you set this to `count` then it will use a simple "count()" query to get the size.

To do this on a per query basis you would do

```java
query.setHint("datanucleus.query.resultSizeMethod", "count");
```

RDBMS : Result Set Type

For RDBMS datastores, `java.sql.ResultSet` defines three possible result set types:

- **forward-only**: the result set is navigable forwards only
- **scroll-sensitive**: the result set is scrollable in both directions and is sensitive to changes in the
datastore

- **scroll-insensitive**: the result set is scrollable in both directions and is insensitive to changes in the datastore.

DataNucleus allows specification of this type as a query extension `datanucleus.rdbms.query.resultSetType`.

To do this on a per query basis you would do

```java
query.setHint("datanucleus.rdbms.query.resultSetType", "scroll-insensitive");
```

The default is *forward-only*. The benefit of the other two is that the result set will be scrollable and hence objects will only be read into memory when accessed. So if you have a large result set you should set this to one of the scrollable values.

**RDBMS : Result Set Control**

DataNucleus RDBMS provides a useful extension allowing control over the ResultSet's that are created by queries. You have at your convenience some properties that give you the power to control whether the result set is read only, whether it can be read forward only, the direction of fetching etc.

To do this on a per query basis you would do

```java
query.setHint("datanucleus.rdbms.query.fetchDirection", "forward");
query.setHint("datanucleus.rdbms.query.resultSetConcurrency", "read-only");
```

Alternatively you can specify these as persistence properties so that they apply to all queries for that PMF/EMF. Again, the properties are

- **datanucleus.rdbms.query.fetchDirection** - controls the direction that the ResultSet is navigated. By default this is forwards only. Use this property to change that.

- **datanucleus.rdbms.query.resultSetConcurrency** - controls whether the ResultSet is read only or updateable.

Bear in mind that not all RDBMS support all of the possible values for these options. That said, they do add a degree of control that is often useful.
JPQL

The Jakarta Persistence specification defines JPQL (a pseudo-OO query language, with SQL-like syntax), for selecting objects from the datastore. To provide a simple example, this is what you would do

```java
Query q = em.createQuery("SELECT p FROM Person p WHERE p.lastName = 'Jones'");
List results = q.getResultList();
```

This finds all "Person" objects with surname of "Jones". You specify all details in the query. The Person specified in the query is the entity name of our entity. This defaults to the name of the class itself, but you can specify it explicitly in the mapping if wanting to use something different.

**SELECT Syntax**

In JPQL queries you define the query in a single string, defining the result, the candidate entity(s), the filter, any grouping, and the ordering. This string has to follow the following pattern

```
SELECT [<result>]
    FROM <from_entities_and_variables>
    [WHERE <filter>]
    [GROUP BY <grouping>] [HAVING <having>]
    [ORDER BY <ordering>]
```

The "keywords" in the query are shown in UPPER CASE, and are case-insensitive.

---

If you set the persistence property `datanucleus.query.jpql.allowRange` to `true` then you can optionally also specify the range of results required in the JPQL string after the ordering. It accepts the following format when this is specified

```
SELECT [<result>]
    FROM <from_entities_and_variables>
    [WHERE <filter>]
    [GROUP BY <grouping>] [HAVING <having>]
    [ORDER BY <ordering>]
    [RANGE <fromInclusive>,<toExclusive>]
```

where `fromInclusive` is the first row to be returned (origin = 0), and `toExclusive` is the row after the last one to be returned.)
FROM Clause

The FROM clause declares query identification variables that represent iteration over objects in the database. The syntax of the FROM clause is as follows:

```
from_clause ::= FROM identification_variable_declaration {,
{identification_variable_declaration | collection_member_declaration}}*
identification_variable_declaration ::= range_variable_declaration { join | fetch_join }
range_variable_declaration ::= entity_name [AS] identification_variable
join ::= join_spec join_association_path_expression [AS] identification_variable
    [join_condition]
fetch_join ::= join_spec FETCH join_association_path_expression
join_association_path_expression ::= join_collection_valued_path_expression |
    join_single_valued_path_expression |
    TREAT(join_collection_valued_path_expression AS subtype) |
    TREAT(join_single_valued_path_expression AS subtype)
join_collection_valued_path_expression ::= identification_variable.{single_valued_embeddable_object_field.}*collection_valued_field
join_single_valued_path_expression ::= identification_variable.{single_valued_embeddable_object_field.}*single_valued_object_field
join_spec ::= [ LEFT [OUTER] | INNER ] JOIN
join_condition ::= ON conditional_expression
collection_member_declaration ::= IN (collection_valued_path_expression) [AS]
identification_variable
```

The FROM clause firstly defines the candidate entity for the query. You can specify the candidate fully-qualified, or you can specify just the entity name. Using our example

```
# Using candidate name fully qualified
SELECT p FROM mydomain.Person p

# Using entity name
SELECT p FROM Person p
```

By default the entity name is the last part of the class name (without the package), but you can specify it in metadata

Firstly, in XML metadata
If the candidate entity has a table using a discriminator, the generated SQL for RDBMS will include a restriction of the possible discriminator values to the candidate and any applicable subclasses. If you want to override this and NOT have a discriminator restriction imposed in the SQL then you provide the query hint `datanucleus.query.dontRestrictDiscriminator` set to `true`.

When using a candidate that has inherited subclasses that are also entities then the query can also return instances of these subclasses. You can set the query "hint" `datanucleus.query.excludeSubclasses` to `true` to only get instances of the candidate entity.

The FROM clause also allows a user to add some explicit joins to related entities, and assign aliases to the joined entities. These are then usable in the filter/ordering/result etc. If you don't add any joins DataNucleus will add joins where they are implicit from the filter expression for example. The FROM clause is of the following structure

```
FROM {candidate_entity} {candidate_alias}
  [[[ LEFT [OUTER] | INNER ] JOIN] join_spec [join_alias] [join_condition] *
```

With JPQL you are explicitly stating that the join across `join_spec` is performed as "LEFT OUTER" or "INNER" (rather than just leaving it to DataNucleus to decide which to use). Note that the `join_spec` can be a relation field, or alternately if you have a Map of non-Entity keys/values then also the Map field. If you provide the `join_alias` then you can use it thereafter in other clauses of the query. The `join_condition` is an optional ON clause that is in addition to navigating along the relation that was specified.

Some examples of FROM clauses.

```
# Join across 2 relations, allowing referral to Address (a) and Owner (o)
SELECT p FROM Person p JOIN p.address a JOIN a.owner o WHERE o.name = 'Fred'

# Join to a Map relation field and access to the key/value of the Map.
SELECT VALUE(om) FROM Company c INNER JOIN c.officeMap om ON KEY(om) = 'London'
```

If you specify "LEFT OUTER FETCH" or "INNER FETCH" (i.e you specify `FETCH`) this means that you
want those fields/properties fetching by this query. This doesn't mean that DataNucleus will definitely fetch them in the same query (because sometimes it is impossible to fetch things like multi-valued fields in a single query) but that it will attempt to fetch all fields that are selected (as well as the ones that are defaulted to EAGER).

DataNucleus Jakarta also allows *RIGHT* OUTER JOIN, though this is not part of the Jakarta Persistence spec.

**FROM : Candidate that is @MappedSuperclass**

In strict Jakarta the entity name cannot be a *MappedSuperclass* entity name. That is, if you have an abstract superclass that is persistable, you cannot query for instances of that superclass and its subclasses. We consider this a significant shortcoming of the querying capability, and allow the entity name to also be of a *MappedSuperclass*. You are unlikely to find this supported in other Jakarta implementations, but then maybe that's why you chose DataNucleus?

**FROM : JOIN ON to another root**

In strict Jakarta you cannot join to another "root" element. That is, you define JOIN syntax to the following element *along a relation* from the previous element. DataNucleus supports joining to a (new) "root" element potentially without any relation. See this example

```
SELECT p FROM Person p LEFT OUTER JOIN Address a ON p.addressName = a.name
```

Here we simply chose an ON clause to join the two roots.

**FROM : JOIN to an embedded element**

In strict Jakarta you cannot join to an embedded element class (of an embeddable). With DataNucleus you can do this, and hence form queries using fields of the embeddable (not available in most other Jakarta providers). See this example, where class *Person* has a Collection of embeddable *Address* objects.

```
SELECT p FROM Person p LEFT OUTER JOIN p.addresses a WHERE a.name = 'Home'
```

**FROM : Control over INNER/OUTER join for implicit joins**
RDBMS: By default if you don't specify the JOIN to some related object in the FROM clause and instead navigate through a 1-1/N-1 relation like "a.owner" then it will join using INNER JOIN. You can change this default by specifying the persistence property (to apply to all queries) or query extension `datanucleus.query.jpql.navigationJoinType` and set it to either "INNERJOIN" or "LEFTOUTERJOIN". You can also set the default for the filter only using the persistence property (to apply to all queries) or query extension `datanucleus.query.jpql.navigationJoinTypeForFilter` and set it to either "INNERJOIN" or "LEFTOUTERJOIN".

**Fetched Fields**

By default a query will fetch fields according to their defined EAGER/LAZY setting, so fields like primitives, wrappers, Dates, and 1-1/N-1 relations will be fetched, whereas 1-N/M-N fields will not be fetched. JPQL allows you to include `FETCH JOIN` as a hint to include relation fields where possible.

For RDBMS datastores any multi-valued (1-N/M-N) field (Collection, array) will be **bulk-fetched** if it is defined to be EAGER or has a `FETCH JOIN`, or is placed in the current EntityGraph. By **bulk-fetched** we mean that there will be a single SQL issued per collection field (hence avoiding the N+1 problem). By default this will be a single SQL per collection of the form `SELECT {relatedObject columns} FROM RELATED_TBL WHERE EXISTS (restrict to the candidate objects involved)`. Note that you can disable this by either not marking multi-valued fields to be fetched, or by setting the query extension `datanucleus.rdbms.query.multivaluedFetch` to `none` (default is `exists` using the single SQL per field as mentioned above).

All non-RDBMS datastores do respect this FETCH JOIN setting, since a collection/map is stored in a single "column" in the object and so is readily retrievable.

Note that you can also make use of Entity Graphs to have fuller control over what is retrieved from each query.

**WHERE clause (filter)**

The most important thing to remember when defining the filter for JPQL is that **think how you would write it in SQL, and its likely the same except for FIELD names instead of COLUMN names**. The filter has to be a boolean expression, and can include the candidate entity, fields/properties, literals, functions, parameters, operators and subqueries.

**GROUP BY/HAVING clauses**

The GROUP BY construct enables the aggregation of values according to a set of properties. The HAVING construct enables conditions to be specified that further restrict the query result. Such conditions are restrictions upon the groups. The syntax of the GROUP BY and HAVING clauses is as follows:
If a query contains both a WHERE clause and a GROUP BY clause, the effect is that of first applying the where clause, and then forming the groups and filtering them according to the HAVING clause. The HAVING clause causes those groups to be retained that satisfy the condition of the HAVING clause. The requirements for the SELECT clause when GROUP BY is used follow those of SQL: namely, any item that appears in the SELECT clause (other than as an argument to an aggregate function) must also appear in the GROUP BY clause. In forming the groups, null values are treated as the same for grouping purposes. Grouping by an entity is permitted. In this case, the entity must contain no serialized state fields or lob-valued state fields. The HAVING clause must specify search conditions over the grouping items or aggregate functions that apply to grouping items. If there is no GROUP BY clause and the HAVING clause is used, the result is treated as a single group, and the select list can only consist of aggregate functions. When a query declares a HAVING clause, it must always also declare a GROUP BY clause.

Some examples

```sql
SELECT p.firstName, p.lastName FROM Person p GROUP BY p.lastName
SELECT p.firstName, p.lastName FROM Person p GROUP BY p.lastName HAVING COUNT(p.lastName) > 1
```

**ORDER BY clause**

The ORDER BY clause allows the objects or values that are returned by the query to be ordered. The syntax of the ORDER BY clause is

```sql
orderby_clause ::= ORDER BY orderby_item {, orderby_item}*
orderby_item ::= state_field_path_expression | result_variable {ASC | DESC}
```

By default your results will be returned in the order determined by the datastore, so don't rely on any particular order. You can, of course, specify the order yourself. You do this using field/property names and ASC/DESC keywords. For example

```sql
field1 ASC, field2 DESC
```

which will sort primarily by field1 in ascending order, then secondarily by field2 in descending order.
Although it is not (yet) standard JPQL, DataNucleus also supports specifying a directive for where NULL values of the ordered field/property go in the order, so the full syntax supported is

```
fieldName {ASC|DESC} {NULLS FIRST|NULLS LAST}
```

This is only supported for a few RDBMS including H2, HSQLDB, PostgreSQL, DB2, Oracle, Derby, Firebird, SQLServer v11+.

**Fields/Properties**

In JPQL you refer to fields/properties in the query by referring to the field/bean name. For example, if you are querying a candidate entity called *Product* and it has a field "price", then you access it like this

```
price < 150.0
```

Note that if you want to refer to a field/property of an entity you can prefix the field by its alias

```
p.price < 150.0
```

You can also chain field references if you have an entity *Product* (alias = p) with a field of (entity) *Inventory*, which has a field *name*, so you could do

```
p.inventory.name = 'Backup'
```

Note that you could alternatively have introduced a *join* to *Inventory* first and then just referenced the *name* field via the *Inventory* join alias.

**Operators**

The operators are listed below in order of decreasing precedence.

- Navigation operator (.)
- Arithmetic operators:
  - +, - unary
  - *, / multiplication and division
  - +, - addition and subtraction
- Logical operators:
  - NOT
Literals

JPQL supports literals of the following types: Number, boolean, character, String, NULL, and temporal. For example, with a numeric literal:

```java
Query q = em.createQuery("SELECT p FROM Person p WHERE p.age = 25");
```

When string literals are specified using single format JPQL they should be surrounded by single-quotes '. For example:

```java
Query q = em.createQuery("SELECT p FROM Person p WHERE p.firstName = 'John'");
```

When temporal literals are specified using string format JPQL they use JDBC escape syntax (see the JDBC spec for full details), namely:

- `{d 'yyyy-mm-dd'}` - a Date
- `{t 'hh:mm:ss'}` - a Time
- `{ts 'yyyy-mm-dd hh:mm:ss.f...'}` - a Timestamp

For example:

```java
Query q = em.createQuery("SELECT p FROM Person p WHERE p.birthDate < {ts '1970-01-01 00:00:00.000000001'}");
```

RDBMS: Parameters v. Literals

When considering whether to embody a literal into a JPQL query, you should consider using a parameter instead. The advantage of using a parameter is that the generated SQL will have a '?' rather than the value. As a result, if you are using a connection pool that supports PreparedStatement caching, this will potentially reuse an existing statement rather than generating a new one each time. If you only ever invoke a query with a single possible value of the parameter then there is no advantage. If you invoke the query with multiple possible values of the parameter then this advantage can be significant.

Parameters

In JPQL queries it is convenient to pass in parameters so we don’t have to define the same query for different values. Let’s take two examples
Named Parameters:
Query q = em.createQuery("SELECT p FROM Person p WHERE p.lastName = :surname AND p.firstName = :forename");
q.setParameter("surname", theSurname);
q.setParameter("forename", theForename);

## Numbered Parameters:
Query q = em.createQuery("SELECT p FROM Person p WHERE p.lastName = ?1 AND p.firstName = ?2");
q.setParameter(1, theSurname);
q.setParameter(2, theForename);

So in the first case we have parameters that are prefixed by : (colon) to identify them as a parameter and we use that name when calling Query.setParameter(). In the second case we have parameters that are prefixed by ? (question mark) and are numbered starting at 1. We then use the numbered position when calling Query.setParameter().

### CASE expressions

For particular use in the result clause, you can make use of a CASE expression where you want to return different things based on some condition(s). Like this

Query q = em.createQuery("SELECT p.personNum, CASE WHEN p.age < 18 THEN 'Youth' WHEN p.age >= 18 AND p.age < 65 THEN 'Adult' ELSE 'Old' END FROM Person p");

So in this case the second result value will be a String, either "Youth", "Adult" or "Old" depending on the age of the person. The BNF structure of the JPQL CASE expression is

CASE WHEN conditional_expression THEN scalar_expression
     {WHEN conditional_expression THEN scalar_expression}* 
     ELSE scalar_expression
END

### JPQL Functions

JPQL provides an SQL-like query language. Just as with SQL, JPQL also supports a range of functions to enhance the querying possibilities. The tables below also mark whether a particular method is supported for evaluation in-memory.

These methods are not available for use with all of the supported datastores to be executed in-datastore. RDBMS, in general, supports the vast majority, whilst MongoDB, Neo4j, Cassandra support a select few methods in-datastore.
Aggregate Functions

There are a series of aggregate functions for aggregating the values of a field for all rows of the results.

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Standard</th>
<th>In-Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>COUNT(field)</td>
<td>Returns the aggregate count of the field (Long)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>MIN(field)</td>
<td>Returns the minimum value of the field (type of the field)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>MAX(field)</td>
<td>Returns the maximum value of the field (type of the field)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>AVG(field)</td>
<td>Returns the average value of the field (Double)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>SUM(field)</td>
<td>Returns the sum of the field value(s) (Long, Double, BigInteger, BigDecimal)</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

String Functions

There are a series of functions to be applied to String fields.

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Standard</th>
<th>In-Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONCAT(str_field, str_field2 [, str_fieldX])</td>
<td>Returns the concatenation of the string fields</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>SUBSTRING(str_field, num1 [, num2])</td>
<td>Returns the substring of the string field starting at position num1, and optionally with the length of num2</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>TRIM([trim_spec] [trim_char] [FROM] str_field)</td>
<td>Returns trimmed form of the string field</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>LOWER(str_field)</td>
<td>Returns the lower case form of the string field</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>UPPER(str_field)</td>
<td>Returns the upper case form of the string field</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>LENGTH(str_field)</td>
<td>Returns the size of the string field (number of characters)</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Function Name</td>
<td>Description</td>
<td>Standard</td>
<td>In-Memory</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>----------</td>
<td>-----------</td>
</tr>
<tr>
<td>LOCATE(str_field1, str_field2 [, num])</td>
<td>Returns position of str_field2 in str_field1 optionally starting at num</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

**Temporal Functions**

There are a series of functions for use with temporal values

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Standard</th>
<th>In-Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_DATE</td>
<td>Returns the current date (day month year) of the datastore server</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>CURRENT_TIME</td>
<td>Returns the current time (hour minute second) of the datastore server</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP</td>
<td>Returns the current timestamp of the datastore server</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>YEAR(dateField)</td>
<td>Returns the year of the specified date in timezone it was stored</td>
<td>×</td>
<td>✓</td>
</tr>
<tr>
<td>MONTH(dateField)</td>
<td>Returns the month of the specified date (1-12) in timezone it was stored</td>
<td>×</td>
<td>✓</td>
</tr>
<tr>
<td>MONTH_JAVA(dateField)</td>
<td>Returns the month of the specified date (0-11) in timezone it was stored</td>
<td>×</td>
<td>✓</td>
</tr>
<tr>
<td>DAY(dateField)</td>
<td>Returns the day of the month of the specified date in timezone it was stored</td>
<td>×</td>
<td>✓</td>
</tr>
<tr>
<td>DAY_OF_WEEK(dateField)</td>
<td>Returns the day of the week of the specified date in timezone it was stored (1-7, with sunday as 1)</td>
<td>×</td>
<td>✓</td>
</tr>
<tr>
<td>HOUR(dateField)</td>
<td>Returns the hour of the specified date in timezone it was stored</td>
<td>×</td>
<td>✓</td>
</tr>
<tr>
<td>MINUTE(dateField)</td>
<td>Returns the minute of the specified date in timezone it was stored</td>
<td>×</td>
<td>✓</td>
</tr>
<tr>
<td>SECOND(dateField)</td>
<td>Returns the second of the specified date in timezone it was stored</td>
<td>×</td>
<td>✓</td>
</tr>
</tbody>
</table>

**Collection Functions**

There are a series of functions for use with collection values
<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Standard</th>
<th>In-Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDEX(collection_field)</td>
<td>Returns index number of the field element when that is the element of an indexed List field.</td>
<td>✓</td>
<td>x</td>
</tr>
<tr>
<td>SIZE(collection_field)</td>
<td>Returns the size of the collection field. Empty collection will return 0</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

### Map Functions

There are a series of functions for use with maps

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Standard</th>
<th>In-Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEY(map_field)</td>
<td>Returns the key of the map</td>
<td>✓</td>
<td>x</td>
</tr>
<tr>
<td>VALUE(map_field)</td>
<td>Returns the value of the map</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>SIZE(map_field)</td>
<td>Returns the size of the map field. Empty map will return 0</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

### Arithmetic Functions

There are a series of functions for arithmetic use

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Standard</th>
<th>In-Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS(numeric_field)</td>
<td>Returns the absolute value of the numeric field</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>SQRT(numeric_field)</td>
<td>Returns the square root of the numeric field</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>
| MOD(num_field1, num_field2) | Returns the modulus of the two numeric fields  
\((num_field1 \% num_field2)\) | ✓        | ✓         |
| ACOS(num_field)     | Returns the arc-cosine of a numeric field                                    | x        | ✓         |
| ASIN(num_field)     | Returns the arc-sine of a numeric field                                      | x        | ✓         |
| ATAN(num_field)     | Returns the arc-tangent of a numeric field                                   | x        | ✓         |
| COS(num_field)      | Returns the cosine of a numeric field                                        | x        | ✓         |
| SIN(num_field)      | Returns the sine of a numeric field                                          | x        | ✓         |
| TAN(num_field)      | Returns the tangent of a numeric field                                       | x        | ✓         |
| DEGREES(num_field)  | Returns the degrees of a numeric field                                       | x        | ✓         |
| RADIANS(num_field)  | Returns the radians of a numeric field                                       | x        | ✓         |
| CEIL(num_field)     | Returns the ceiling of a numeric field                                       | x        | ✓         |
### Function Name

<table>
<thead>
<tr>
<th>Description</th>
<th>Standard</th>
<th>In-Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLOOR(num_field)</td>
<td></td>
<td>✓</td>
</tr>
<tr>
<td>Returns the floor of a numeric field</td>
<td></td>
<td>✓</td>
</tr>
<tr>
<td>LOG(num_field)</td>
<td></td>
<td>✓</td>
</tr>
<tr>
<td>Returns the natural logarithm of a numeric field</td>
<td></td>
<td>✓</td>
</tr>
<tr>
<td>EXP(num_field)</td>
<td></td>
<td>✓</td>
</tr>
<tr>
<td>Returns the exponent of a numeric field</td>
<td></td>
<td>✓</td>
</tr>
<tr>
<td>POWER(numeric_field, numeric_value)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns the numeric field to the specified power</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ROUND(num_field[, decimal_places])</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns the rounded value of a numeric field (optionally to a number of decimal places)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Other Functions

You have a further function available

<table>
<thead>
<tr>
<th>Description</th>
<th>Standard</th>
<th>In-Memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>FUNCTION(name, [arg1 [,arg2 ...]])</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>Executes the specified SQL function &quot;name&quot; with the defined arguments. <strong>RDBMS only</strong></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For example, this executes the SQL function 'date_part' (where it is available) with 2 arguments, a Date, and a format. Clearly there are better ways of handling dates than this so it serves simply as an example of invocation

```
SELECT FUNCTION('date_part', myDate, 'YYYY-MM-DD') FROM ...
```

### Geospatial Functions

When querying spatial data you can make use of a set of spatial methods on the various Java geometry types. The list contains all of the functions detailed in Section 3.2 of the OGC Simple Features specification. Additionally DataNucleus provides some commonly required methods like bounding box test and datastore specific functions. The following tables list all available functions as well as information about which RDBMS implement them. An entry in the "Result" column indicates, whether the function may be used in the result part of a JPQL query.

### Functions on Type Geometry (OGC SF 3.2.10)
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.dimension(Geometry)</td>
<td>Returns the dimension of the Geometry.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.geometryType(Geometry)</td>
<td>Returns the name of the instantiable subtype of Geometry.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.asText(Geometry)</td>
<td>Returns the well-known textual representation.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.asBinary(Geometry)</td>
<td>Returns the well-known binary representation.</td>
<td>X</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.srid(Geometry)</td>
<td>Returns the Spatial Reference System ID for this Geometry.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.isEmpty(Geometry)</td>
<td>TRUE if this Geometry corresponds to the empty set.</td>
<td>! [1]</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.isSimple(Geometry)</td>
<td>TRUE if this Geometry is simple, as defined in the Geometry Model.</td>
<td>! [1]</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.boundary(Geometry)</td>
<td>Returns a Geometry that is the combinatorial boundary of the Geometry.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.envelope(Geometry)</td>
<td>Returns the rectangle bounding Geometry as a Polygon.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

[1] Oracle does not allow boolean expressions in the SELECT-list.

**Functions on Type Point (OGC SF 3.2.11)**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.x(Point)</td>
<td>Returns the x-coordinate of the Point as a Double.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.y(Point)</td>
<td>Returns the y-coordinate of the Point as a Double.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

**Functions on Type Curve (OGC SF 3.2.12)**
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.startPoint(Curve)</td>
<td>Returns the first point of the Curve.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.endPoint(Curve)</td>
<td>Returns the last point of the Curve.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.isRing(Curve)</td>
<td>Returns TRUE if Curve is closed and simple.</td>
<td>!</td>
<td>[1]</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

[1] Oracle does not allow boolean expressions in the SELECT-list.

**Functions on Type Curve / MultiCurve (OGC SF 3.2.12, 3.2.17)**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.isClosed(Curve)</td>
<td>Returns TRUE if Curve is closed, i.e., if StartPoint(Curve) = EndPoint(Curve).</td>
<td>!</td>
<td>[1]</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.length(Curve)</td>
<td>Returns the length of the Curve.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

[1] Oracle does not allow boolean expressions in the SELECT-list.

**Functions on Type LineString (OGC SF 3.2.13)**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.numPoints(LineString)</td>
<td>Returns the number of points in the LineString.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.pointN(LineString, Integer)</td>
<td>Returns Point n.</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

**Functions on Type Surface / MultiSurface (OGC SF 3.2.14, 3.2.18)**
**Method** | **Description** | **Result** | **PostGIS** | **MySQL** | **Oracle Spatial**
--- | --- | --- | --- | --- | ---
Spatial.centroid(Surface) | Returns the centroid of Surface, which may lie outside of it. | ✔ | ✔ | ✗ | ✔
Spatial.pointOnSurface(Surface) | Returns a Point guaranteed to lie on the surface. | ✔ | ✔ | ✗ | ✔
Spatial.area(Surface) | Returns the area of Surface. | ✔ | ✔ | ✔ | ✔

[1] MySQL does not implement these functions.

**Functions on Type Polygon (OGC SF 3.2.15)**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
</table>
Spatial.exteriorRing(Polygon) | Returns the exterior ring of Polygon. | ✔ | ✔ | ✔ | ✔
Spatial.numInteriorRing(Polygon) | Returns the number of interior rings. | ✔ | ✔ | ✔ | ✔
Spatial.interiorRingN(Polygon, Integer) | Returns the nth interior ring. | ✔ | ✔ | ✔ | ✔

**Functions on Type GeomCollection (OGC SF 3.2.16)**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
</table>
Spatial.numGeometries(GeomCollection) | Returns the number of geometries in the collection. | ✔ | ✔ | ✔ | ✔
Spatial.geometryN(GeomCollection, Integer) | Returns the nth geometry in the collection. | ✔ | ✔ | ✔ | ✔

**Functions that test Spatial Relationships (OGC SF 3.2.19)**
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.equals(Geometry, Geometry)</td>
<td>TRUE if the two geometries are spatially equal.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td></td>
</tr>
<tr>
<td>Spatial.disjoint(Geometry, Geometry)</td>
<td>TRUE if the two geometries are spatially disjoint.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td></td>
</tr>
<tr>
<td>Spatial.touches(Geometry, Geometry)</td>
<td>TRUE if the first Geometry spatially touches the other Geometry.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td></td>
</tr>
<tr>
<td>Spatial.within(Geometry, Geometry)</td>
<td>TRUE if first Geometry is completely contained in second Geometry.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td></td>
</tr>
<tr>
<td>Spatial.overlaps(Geometry, Geometry)</td>
<td>TRUE if first Geometries is spatially overlapping the other Geometry.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td></td>
</tr>
<tr>
<td>Spatial.crosses(Geometry, Geometry)</td>
<td>TRUE if first Geometry crosses the other Geometry.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td>![3]</td>
</tr>
<tr>
<td>Spatial.intersects(Geometry, Geometry)</td>
<td>TRUE if first Geometry spatially intersects the other Geometry.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td></td>
</tr>
<tr>
<td>Spatial.contains(Geometry, Geometry)</td>
<td>TRUE if second Geometry is completely contained in first Geometry.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td></td>
</tr>
<tr>
<td>Spatial.relate(Geometry, Geometry, String)</td>
<td>TRUE if the spatial relationship specified by the patternMatrix holds.</td>
<td>![1]</td>
<td>![2]</td>
<td>![1]</td>
<td></td>
</tr>
</tbody>
</table>

[1] Oracle does not allow boolean expressions in the SELECT-list. [2] MySQL does not implement these functions according to the specification. They return the same result as the corresponding MBR-based functions.

**Function on Distance Relationships (OGC SF 3.2.20)**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.distance(Geometry, Geometry)</td>
<td>Returns the distance between the two geometries.</td>
<td>✔️ ✔️ ✔️ ✔️</td>
<td>✔️ ✔️ ✔️ [1]</td>
<td>✔️ ✔️ ✔️</td>
<td>✔️ ✔️</td>
</tr>
</tbody>
</table>

[1] MariaDB 5.3.3+ implements this.
### Functions that implement Spatial Operators (OGC SF 3.2.21)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.intersection(Geometry, Geometry)</td>
<td>Returns a Geometry that is the set intersection of the two geometries.</td>
<td>✓</td>
<td>✓</td>
<td>✗</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.difference(Geometry, Geometry)</td>
<td>Returns a Geometry that is the closure of the set difference of the two geometries.</td>
<td>✓</td>
<td>✓</td>
<td>✗</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.union(Geometry, Geometry)</td>
<td>Returns a Geometry that is the set union of the two geometries.</td>
<td>✓</td>
<td>✓</td>
<td>✗</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.symDifference(Geometry, Geometry)</td>
<td>Returns a Geometry that is the closure of the set symmetric difference of the two geometries.</td>
<td>✓</td>
<td>✓</td>
<td>✗</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.buffer(Geometry, Double)</td>
<td>Returns a Geometry defined by buffering a distance around the Geometry.</td>
<td>✓</td>
<td>✓</td>
<td>✗</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.convexHull(Geometry)</td>
<td>Returns a Geometry that is the convex hull of the Geometry.</td>
<td>✓</td>
<td>✓</td>
<td>✗</td>
<td>✓</td>
</tr>
</tbody>
</table>

[1] These functions are currently not implemented in MySQL. They may appear in future releases.

### Functions for Constructing a Geometry Value given its Well-known Representation (OGC SF 3.2.6, 3.2.7)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result</th>
<th>PostGIS</th>
<th>MySQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.geomFromText(String, Integer)</td>
<td>Construct a Geometry given its well-known textual representation.</td>
<td>✗</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.pointFromText(String, Integer)</td>
<td>Construct a Point given its well-known textual representation.</td>
<td>✗</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.lineFromText(String, Integer)</td>
<td>Construct a LineString given its well-known textual representation.</td>
<td>✗</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.polyFromText(String, Integer)</td>
<td>Construct a Polygon given its well-known textual representation.</td>
<td>✗</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Spatial.mPointFromText(String, Integer)</td>
<td>Construct a MultiPoint given its well-known textual representation.</td>
<td>✗</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
<td>Result</td>
<td>PostGIS</td>
<td>MySQL</td>
<td>Oracle Spatial</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>------------------------------------------------------------------</td>
<td>--------</td>
<td>---------</td>
<td>-------</td>
<td>----------------</td>
</tr>
<tr>
<td>Spatial.mLineFromText(String, Integer)</td>
<td>Construct a MultiLineString given its well-known textual representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.mPolyFromText(String, Integer)</td>
<td>Construct a MultiPolygon given its well-known textual representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.geomCollFromText(Object, Integer)</td>
<td>Construct a GeometryCollection given its well-known textual representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.geomFromWKB(Object, Integer)</td>
<td>Construct a Geometry given its well-known binary representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.pointFromWKB(Object, Integer)</td>
<td>Construct a Point given its well-known binary representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.lineFromWKB(Object, Integer)</td>
<td>Construct a LineString given its well-known binary representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.polyFromWKB(Object, Integer)</td>
<td>Construct a Polygon given its well-known binary representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.mPointFromWKB(Object, Integer)</td>
<td>Construct a MultiPoint given its well-known binary representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.mLineFromWKB(Object, Integer)</td>
<td>Construct a MultiLineString given its well-known binary representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.mPolyFromWKB(Object, Integer)</td>
<td>Construct a MultiPolygon given its well-known binary representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>Spatial.geomCollFromWKB(Object, Integer)</td>
<td>Construct a GeometryCollection given its well-known binary representation.</td>
<td></td>
<td>✔</td>
<td>✔</td>
<td>✔</td>
</tr>
</tbody>
</table>

[1] These functions can’t be used in the return part because it’s not possible to determine the return type from the parameters.

**Supplementary Functions**

These functions are only supported on certain RDBMS.
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Result PostGIS</th>
<th>My SQL</th>
<th>Oracle Spatial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spatial.bboxTest(Geometry, Geometry)</td>
<td>Returns TRUE if if the bounding box of the first Geometry overlaps second Geometry’s bounding box</td>
<td>![1]</td>
<td>✔</td>
<td>✔</td>
</tr>
<tr>
<td>PostGIS.bboxOverlapsLeft(Geometry, Geometry)</td>
<td>The PostGIS &amp;&lt; operator returns TRUE if the bounding box of the first Geometry overlaps or is to the left of second Geometry's bounding box</td>
<td>✔</td>
<td>✗</td>
<td>✗</td>
</tr>
<tr>
<td>PostGIS.bboxOverlapsRight(Geometry, Geometry)</td>
<td>The PostGIS &amp;&lt; operator returns TRUE if the bounding box of the first Geometry overlaps or is to the right of second Geometry’s bounding box</td>

[1] Oracle does not allow boolean expressions in the SELECT-list.

Examples

The following sections provide some examples of what can be done using spatial methods in JPQL queries. In the examples we use a class from the test suite. Here's the source code for reference:

```java
package mydomain.samples.pggeometry;

import org.postgis.LineString;

public class SampleLineString {
    private long id;
    private String name;
    private LineString geom;

    public SampleLineString(long id, String name, LineString lineString) {
        this.id = id;
        this.name = name;
        this.geom = lineString;
    }

    public long getId() {
        return id;
    }
    ....
}
```
Example 1 - Spatial Function in the Filter of a Query

This example shows how to use spatial functions in the filter of a query. The query returns a list of SampleLineString(s) whose line string has a length less than the given limit.

```
Query q = em.createQuery("SELECT s FROM SampleLineString s WHERE s.geom IS NOT NULL AND Spatial.length(s.geom) < :limit");
q.setParameter("limit", new Double(100.0));
List list = q.getResultList();
```

Example 2 - Spatial Function in the Result Part of a Query

This time we use a spatial function in the result part of a query. The query returns the length of the line string from the selected SampleLineString

```
q = em.createQuery("SELECT Spatial.pointN(s.geom, 2) FROM SampleLineString s WHERE s.id == :id");
q.setParameter("id", new Long(1001));
Geometry point = q.getSingleResult();
```

Example 3 - Nested Functions

You may want to use nested functions in your query. This example shows how to do that. The query returns a list of SampleLineString(s), whose end point spatially equals a given point.

```
Point point = new Point("SRID=4326;POINT(110 45)"");
Query q = em.createQuery("SELECT s FROM SampleLineString s WHERE s.geom IS NOT NULL AND Spatial.equals(Spatial.endPoint(s.geom), :point)"");
q.setParameter("point", point);
List list = q.getResultList();
```
Collection Fields

Where you have a collection field, often you want to navigate it to query based on some filter for the element. To achieve this, you can clearly JOIN to the element in the FROM clause. Alternatively you can use the MEMBER OF keyword. Let's take an example, you have a field which is a Collection of Strings, and want to return the owner object that has an element that is "Freddie".

```java
Query q = em.createQuery("SELECT p.firstName, p.lastName FROM Person p WHERE 'Freddie' MEMBER OF p.nicknames");
```

Beyond this, you can also make use of the collection functions and use the size of the collection for example.

Map Fields

Where you have a map field, often you want to navigate it to query based on some filter for the key or value. Let's take an example, you want to return the value for a particular key in the map of an owner.

```java
Query q = em.createQuery("SELECT VALUE(p.addresses) FROM Person p WHERE KEY(p.addresses) = 'London Flat'");
```

Beyond this, you can also make use of the map functions and use the size of the map for example.

> In the Jakarta Persistence spec they allow a user to interchangeably use "p.addresses" to refer to the value of the Map. Whilst DataNucleus supports this, we advise using explicit `VALUE(field)` since it is clearer the intent and makes for more readable queries.

Subqueries

In strict JPQL you can only have subqueries in WHERE or HAVING clauses. DataNucleus additionally allows them in the SELECT, GROUP and ORDER clauses.

With JPQL the user has a very flexible query syntax which allows for querying of the vast majority of data components in a single query. In some situations it is desirable for the query to utilise the results of a separate query in its calculations. JPQL also allows the use of subqueries. Here's an example

```sql
SELECT e FROM Employee e
WHERE e.salary > (SELECT avg(f.salary) FROM Employee f)
```

So we want to find all Employees that have a salary greater than the average salary. The subquery must be in parentheses (brackets). Note that we have defined the subquery with an alias of "f",
whereas in the outer query the alias is "e".

**ALL/ANY/SOME Expressions**

One use of subqueries with JPQL is where you want to compare with some or all of a particular expression. To give an example

```sql
SELECT emp FROM Employee emp
WHERE emp.salary > ALL (SELECT m.salary FROM Manager m WHERE m.department = emp.department)
```

So this returns all employees that earn more than all managers in the same department! You can also compare with SOME/ANY, like this

```sql
SELECT emp FROM Employee emp
WHERE emp.salary > ANY (SELECT m.salary FROM Manager m WHERE m.department = emp.department)
```

So this returns all employees that earn more than any one Manager in the same department.

**EXISTS Expressions**

Another use of subqueries in JPQL is where you want to check on the existence of a particular thing. For example

```sql
SELECT DISTINCT emp FROM Employee emp
WHERE EXISTS (SELECT emp2 FROM Employee emp2 WHERE emp2 = emp.spouse)
```

So this returns the employees that have a partner also employed.

**Specify candidates to query over**

With Jakarta Persistence you always query objects of the candidate type in the datastore. DataNucleus extends this and allows you to provide a Collection of candidate objects that will be queried (rather than going to the datastore), and it will perform the querying "in-memory". You set the candidates like this

```java
Query query = em.createQuery("SELECT p FROM Products p WHERE ...");
((org.datanucleus.api.jakarta.JakartaQuery)query).getInternalQuery().setCandidates(myCandidates);
List<Product> results = query.getResultList();
```
Range of Results

With JPQL you can select the range of results to be returned. For example if you have a web page and you are paginating the results of some search, you may want to get the results from a query in blocks of 20 say, with results 0 to 19 on the first page, then 20 to 39, etc. You can facilitate this as follows:

```java
Query q = em.createQuery("SELECT p FROM Person p WHERE p.age > 20");
q.setFirstResult(0);
q.setMaxResults(20);
```

So with this query we get results 0 to 19 inclusive.

Query Result

The query result (SELECT) clause allows a user to select particular fields, objects etc. The syntax of the query result clause is as follows:

```
select_clause ::= SELECT [DISTINCT] select_item {, select_item}*
select_item ::= select_expression [[AS] result_variable]
select_expression ::= single_valued_path_expression | scalar_expression |
aggregate_expression |
   identification_variable | OBJECT(identification_variable) | constructor_expression
constructor_expression ::= NEW constructor_name ( constructor_item {,
constructor_item}*)
constructor_item ::= single_valued_path_expression | scalar_expression |
aggregate_expression |
   identification_variable
```

Whilst the majority of the time you will want to return instances of a candidate class, JPQL also allows you to return customised results. Consider the following example:

```java
Query q = em.createQuery("SELECT p.firstName, p.lastName FROM Person p WHERE p.age > 20");
List<Object[]> results = q.getResultList();
```

this returns the first and last name for each Person meeting that filter. Obviously we may have some container class that we would like the results returned in, so if we change the query to this

```java
Query<PersonName> q = em.createQuery("SELECT p.firstName, p.lastName FROM Person p WHERE p.age > 20", PersonName.class);
List<PersonName> results = q.getResultList();
```

so each result is a PersonName, holding the first and last name. This result class needs to match one
of the following structures

- Constructor taking arguments of the same types and the same order as the result clause. An instance of the result class is created using this constructor. For example

```java
public class PersonName
{
    protected String firstName = null;
    protected String lastName = null;
    public PersonName(String first, String last)
    {
        this.firstName = first;
        this.lastName = last;
    }
}
```

- Default constructor, and setters for the different result columns, using the alias name for each column as the property name of the setter. For example

```java
public class PersonName
{
    protected String firstName = null;
    protected String lastName = null;
    public PersonName()
    {
    }
    public void setFirstName(String first) {this.firstName = first;}
    public void setLastName(String last) {this.lastName = last;}
}
```

- Default constructor, and a method `void put(Object aliasName, Object value)`

Note that if the setter property name doesn’t match the query result component name, you should use `AS {alias}` in the query so they are the same.

**Tuples**

A special case, where you don’t have a result class but want to easily extract multiple columns in the form of a `Tuple`. Jakarta provides a special class `jakarta.persistence.Tuple` to supply as the result class in the above call. From that you can get hold of the column aliases, and their values.
Query Execution

There are two ways to execute a JPQL query. When you know it will return 0 or 1 results you call

```java
Object result = query.getSingleResult();
```

If however you know that the query will return multiple results, or you just don’t know then you would call

```java
List results = query.getResultList();
```

When using RDBMS all parts of a query are evaluated in-datastore. When using LDAP, Excel, ODF, XML, JSON, GoogleStorage, AmazonS3 any query filter/ordering etc is evaluated in-memory. When using Neo4j, HBase, MongoDB and Cassandra any query filter/ordering etc are evaluated in-datastore where possible, with the remainder evaluated in-memory.

Query Execution In-Memory

The typical use of a JPQL query is to translate it into the native query language of the datastore and return objects matched by the query. For many (usually non-RDBMS) datastores it is simply impossible to support the full JPQL syntax in the datastore native query language and so it is necessary to evaluate the query in-memory. This means that we evaluate as much as we can in the datastore and then instantiate those objects and evaluate further in-memory. Here we document the current capabilities of in-memory evaluation in DataNucleus.

- Subqueries using ALL, ANY, SOME, EXISTS are not currently supported for use in-memory.
- MEMBER OF syntax is not currently supported for use in-memory.
To enable evaluation in memory you specify the query hint `datanucleus.query.evaluateInMemory` to `true` as follows:

```java
query.setHint("datanucleus.query.evaluateInMemory","true");
```

In-memory JPQL evaluation does not support JOINs currently, or correlated subqueries. You should omit such things from your query and try to evaluate them manually in your own code.

**Named Query**

With the Jakarta Persistence API you can either define a query at runtime, or define it in the MetaData/annotations for a class and refer to it at runtime using a symbolic name. This second option means that the method of invoking the query at runtime is much simplified. To demonstrate the process, let's say we have a class called `Product` (something to sell in a store). We define the Jakarta Meta-Data for the class in the normal way, but we also have some query that we know we will require, so we define the following in the Meta-Data:

```xml
<entity class="Product">
...
  <named-query name="SoldOut"><![CDATA[
    SELECT p FROM Product p WHERE p.status = "Sold Out"
  ]]></named-query>
</entity>
```

Or using annotations:

```java
@Entity
@NamedQuery(name="SoldOut", query="SELECT p FROM Product p WHERE p.status = 'Sold Out'")
public class Product {...}
```

DataNucleus also supports specifying this using `@NamedQuery` annotation in non-Entity classes. This is beyond the Jakarta Persistence spec, but is very useful in real applications.

Above we have a JPQL query called “SoldOut” defined for the class `Product` that returns all Products (and subclasses) that have a `status` of “Sold Out”. To execute this query we would do as follows:

```java
Query query = em.createNamedQuery("SoldOut");
List<Product> results = query.getResultList();
```
Saving a Query as a Named Query

You can save a query as a named query like this

```java
Query q = em.createQuery("SELECT p FROM Product p WHERE ...");
...
emf.addNamedQuery("MyQuery", q);
```

DataNucleus also allows you to create a query, and then save it as a "named" query directly with the query. You do this as follows

```java
Query q = em.createQuery("SELECT p FROM Product p WHERE ...");
((org.datanucleus.api.jakarta.JakartaQuery)q).saveAsNamedQuery("MyQuery");
```

With both methods you can thereafter access the query via

```java
Query q = em.createNamedQuery("MyQuery");
```

**JPQL : SQL Generation for RDBMS**

With a JPQL query running on an RDBMS the query is compiled into SQL. Here we give a few examples of what SQL is generated. You can of course try this for yourself observing the content of the DataNucleus log, or by using the following vendor extension

```java
Query q = em.createQuery(...);
List results = q.getResultList();
String sql = (String)((org.datanucleus.api.jakarta.JakartaQuery)q).getNativeQuery();
```

For non-RDBMS datastores this can return other object types.

In JPQL you specify a candidate class and its alias (identifier). In addition you can specify joins with their respective alias. The DataNucleus implementation of JPQL will preserve these aliases in the generated SQL.

```sql
# JPQL:
SELECT p FROM Person p INNER JOIN p.bestFriend AS B

# SQL:
SELECT P.ID
FROM PERSON P INNER JOIN PERSON B ON B.ID = P.BESTFRIEND_ID
```
With the JPQL *MEMBER OF* syntax this is typically converted into an EXISTS query.

```java
# JPQL:
SELECT DISTINCT p FROM Person p WHERE :param MEMBER OF p.friends

# SQL:
SELECT DISTINCT P.ID FROM PERSON P
WHERE EXISTS (  
    SELECT 1 FROM PERSON_FRIENDS P_FRIENDS, PERSON P_FRIENDS_1  
    WHERE P_FRIENDS.PERSON_ID = P.ID  
    AND P_FRIENDS_1.GLOBAL_ID = P_FRIENDS.FRIEND_ID  
    AND 101 = P_FRIENDS_1.ID)
```

**JPQL DELETE Queries**

The Jakarta Persistence specification defines a mode of JPQL for deleting objects from the datastore. **NOTE**: this will not invoke any cascading defined on a field basis, with only datastore-defined Foreign Keys cascading. Additionally related objects already in-memory will not be updated.

**DELETE Syntax**

The syntax for deleting records is very similar to selecting them

```
DELETE FROM [<candidate-class> [[AS] {alias}]] [WHERE <filter>]
```

The "keywords" in the query are shown in UPPER CASE, and are case-insensitive.

```java
Query query = em.createQuery("DELETE FROM Person p WHERE firstName = 'Fred' ");
int numRowsDeleted = query.executeUpdate();
```

**JPQL UPDATE Queries**

The Jakarta Persistence specification defines a mode of JPQL for updating objects in the datastore.

This will not invoke any cascading defined on a field basis, with only datastore-defined Foreign Keys cascading. Additionally related objects already in-memory will not be updated

**UPDATE Syntax**

The syntax for updating records is very similar to selecting them

```
UPDATE [<candidate-class> [[AS] {alias}]] SET item1=value1, item2=value2 [WHERE <filter>]
```
The "keywords" in the query are shown in UPPER CASE, and are case-insensitive.

```
Query query = em.createQuery("UPDATE Person p SET p.salary = 10000 WHERE age = 18");
int numRowsUpdated = query.executeUpdate();
```

In strict Jakarta you cannot use a subquery in the UPDATE clause. With DataNucleus Jakarta you can do this so, for example, you can set a field to the result of a subquery.

```
Query query = em.createQuery("UPDATE Person p SET p.salary = (SELECT MAX(p2.salary)
FROM Person p2 WHERE age < 18) WHERE age = 18");
```

**JPQL Syntax Strictness**

By default DataNucleus allows some extensions in syntax over strict JPQL (as defined by the Jakarta Persistence spec). To allow only strict JPQL you can do as follows

```
Query query = em.createQuery(...);
query.setHint("datanucleus.query.jpql.strict", "true");
```

**JPQL Syntax BNF Notation**

The BNF defining the JPQL query language syntax is shown below.

```
QL_statement ::= select_statement | update_statement | delete_statement
select_statement ::= select_clause from_clause [where_clause] [groupby_clause]
                   [having_clause] [orderby_clause]
update_statement ::= update_clause [where_clause]
delete_statement ::= delete_clause [where_clause]
from_clause ::= FROM identification_variable_declaration
               {}, {identification_variable_declaration | collection_member_declaration}]*
identification_variable_declaration ::= range_variable_declaration { join | fetch_join }
range_variable_declaration ::= entity_name [AS] identification_variable
join ::= join_spec join_association_path_expression [AS] identification_variable
fetch_join ::= join_spec FETCH join_association_path_expression
join_spec ::= [ LEFT [OUTER] | INNER ] JOIN
join_association_path_expression ::= join_collection_valued_path_expression |

simple_when_clause ::= WHEN scalar_expression THEN scalar_expression 
coalesce_expression ::= COALESCE(scalar_expression {, scalar_expression}+)
nullif_expression ::= NULLIF(scalar_expression, scalar_expression)
Criteria

In Jakarta Persistence there is a query API referred to as "criteria", that broadly mirrors the JPQL query syntax. This is really an API allowing the construction of queries expression by expression, and optionally making it type-safe. It provides two ways of specifying a field/property; the first way is using Strings, and the second using a Static MetaModel. The advantages of the Static MetaModel are that it means that your queries are refactorable if you rename a field, and also that you can dynamically generate the query. Each example will be expressed in both ways where appropriate so you can see the difference.

Creating a Criteria query

To use the Jakarta Criteria API, firstly you need to create a CriteriaQuery object for the candidate in question, and set the candidate, its alias, and the result to be of the candidate type. We make use of the CriteriaBuilder to do this

```java
CriteriaBuilder cb = emf.getCriteriaBuilder();
CriteriaQuery<Person> crit = cb.createQuery(Person.class);
Root<Person> candidateRoot = crit.from(Person.class);
candidateRoot.alias("p");
crit.select(candidateRoot);
```

So what we have there equates to

```
SELECT p FROM mydomain.Person p
```

For a complete list of all methods available on CriteriaBuilder, refer to javadoc

For a complete list of all methods available on CriteriaQuery, refer to javadoc

JPQL equivalent of the Criteria query

If you ever want to know what is the equivalent JPQL string-based query for your Criteria, just print out criteriaQuery.toString(). This is not part of the Jakarta Persistence spec, but something that we feel is very useful so is provided as a DataNucleus vendor extension. So, for example, the criteria query above would result in the following from crit.toString()

```
SELECT p FROM mydomain.Person p
```
Criteria API : Result clause

The basic Criteria query above is fine, but you may want to define a result other than the candidate. To do this we need to use the Criteria API.

```java
Path nameField = candidateRoot.get("name");
crit.select(nameField);
```

which equates to

```
SELECT p.name
```

Note that here we accessed a field by its name (as a String). We could easily have accessed it via the Static MetaModel too, like this

```java
Path nameField = candidateRoot.get(Person_.name);
crit.select(nameField);
```

Criteria API : FROM clause joins

The basic Criteria query above is fine, but you may want to define some explicit joins. To do this we need to use the Criteria API.

```java
// String-based:
ManagedType personType = emf.getMetamodel().type(Person_.class);
Attribute addressAttr = personType.getAttribute("address");
Join addressJoin = candidateRoot.join((SingularAttribute)addressAttr);
addressJoin.alias("a");

// MetaModel-based:
Join<Person, Address> addressJoin = candidateRoot.join(Person_.address);
addressJoin.alias("a");
```

which equates to

```
FROM mydomain.Person p JOIN p.address a
```

Criteria API : WHERE clause

Should we want to impose a WHERE clause filter, we use the where method on CriteriaQuery, using CriteriaBuilder to build the WHERE clause.
// String-based:
Predicate nameEquals = cb.equal(candidateRoot.get("name"), "First");
crit.where(nameEquals);

// MetaModel-based:
Predicate nameEquals = cb.equal(candidateRoot.get(Person_.name), "First");
crit.where(nameEquals);

which equates to

WHERE p.name = 'FIRST'

You can also invoke functions, so a slight variation on this clause would be

// String-based:
Predicate nameUpperEquals = cb.equal(cb.upper(candidateRoot.get("name")), "FIRST");
crit.where(nameUpperEquals);

// MetaModel-based:
Predicate nameUpperEquals = cb.equal(cb.upper(candidateRoot.get(Person_.name)), "FIRST");
crit.where(nameUpperEquals);

which equates to

WHERE (UPPER(p.name) = 'FIRST')

You can combine predicates into AND/OR structures like this

// String-based:
Predicate nameEquals = cb.equal(candidateRoot.get("name"), "First");
Predicate ageEquals = cb.equal(candidateRoot.get("age"), 18);
crit.where(cb.and(nameEquals, ageEquals));

// MetaModel-based:
Predicate nameEquals = cb.equal(candidateRoot.get(Person_.name), "First");
Predicate ageEquals = cb.equal(candidateRoot.get(Person_.age), 18);
crit.where(b.and(nameEquals, ageEquals));

which equates to

WHERE p.name = 'FIRST' AND p.age = 18
// String-based:
Predicate nameEquals = cb.equal(candidateRoot.get("name"), "First");
Predicate ageEquals = cb.equal(candidateRoot.get("age"), 18);
crit.where(cb.or(nameEquals, ageEquals));

// MetaModel-based:
Predicate nameEquals = cb.equal(candidateRoot.get(Person_.name), "First");
Predicate ageEquals = cb.equal(candidateRoot.get(Person_.age), 18);
crit.where(b.or(nameEquals, ageEquals));

which equates to

WHERE p.name = 'FIRST' OR p.age = 18

Criteria API : Ordering

Should we want to impose an ORDER clause, we use the orderBy method on CriteriaQuery, using CriteriaBuilder to build the ORDERing clause.

// String-based:
Order orderName = cb.desc(candidateRoot.get("name"));
crit.orderBy(orderName);

// MetaModel-based:
Order orderName = cb.desc(candidateRoot.get(Person_.name));
crit.orderBy(orderName);

which equates to

ORDER BY p.name DESC

DataNucleus provides an extension to the Jakarta Criteria API in its jakarta.persistence-2.2.jar where you have additional methods to specify where NULL values are placed in the ordering. Like this

Order orderName = cb.desc(candidateRoot.get("name"));
orderName.nullsFirst();

which will put NULL values of that field before other values. This equates to

ORDER BY p.name DESC NULLS FIRST

Similarly there is a method nullsLast if you wanted nulls to be put at the end of the list.
Criteria API : Parameters

Another common thing we would want to do is specify input parameters. We define these using the `CriteriaBuilder` API. Let's take an example of a WHERE clause with parameters.

```
// String-based:
ParameterExpression param1 = cb.parameter(String.class, "myParam1");
Predicate nameEquals = cb.equal(candidateRoot.get("name"), param1);
crit.where(nameEquals);

// MetaModel-based:
ParameterExpression param1 = cb.parameter(String.class, "myParam1");
Predicate nameEquals = cb.equal(candidateRoot.get(Person_.name), param1);
crit.where(nameEquals);
```

which equates to

```
WHERE (p.name = :myParam)
```

Don’t forget to set the value of the parameters before executing the query!

Criteria API : Subqueries

You can also make use of subqueries with Criteria.

In this example we are going to search for all `Employee(s)` where the salary is below the average of all `Employees`. In JPQL this would be written as

```
SELECT e FROM Employee e WHERE (e.salary < SELECT AVG(e2.salary) FROM Employee e2)
```

With Criteria we do it like this. Firstly we create the outer query, then create the subquery, and then place the subquery in the outer query.
```
CriteriaQuery<Employee> crit = cb.createQuery(Employee.class);
Root<Employee> candidate = crit.from(Employee.class);
candidate.alias("e");
crit.select(candidate);

// Create subquery for the average salary of all Employees
Subquery<Double> subCrit = crit.subquery(Double.class);
Root<Employee> subCandidate = subCrit.from(Employee.class);
subCandidate.alias("e2");
Subquery<Double> avgSalary = subCrit.select(cb.avg(subCandidate.get("salary")));

// Add WHERE clause to outer query, linking to subquery
Path eSalaryField = candidate.get("salary");
Predicate lessThanAvgSalary = cb.lessThan(eSalaryField, avgSalary);
crit.where(lessThanAvgSalary);
```

**Criteria API : IN operator**

You can make use of the IN operator with Criteria, like this

```
List<String> nameOptions = new ArrayList<String>();
nameOptions.add("Fred");
nameOptions.add("George");

Path nameField = candidateRoot.get("name");
Predicate nameIn = nameField.in(nameOptions);
```

so this generates the equivalent of this JPQL

```
name IN ('Fred', 'George')
```

An alternative way of doing this is via the CriteriaBuilder

```
In nameIn = cb.in(candidateRoot.get("name");
nameIn.value("Fred");
nameIn.value("George");
crit.where(nameIn);
```

**Criteria API : CASE expressions**

You can make use of CASE expressions with Criteria, like this
Path<Integer> ageVar = candidate.get(Person_.age);
Predicate infantAge = cb.lessThan(ageVar, 5);
Predicate schoolAge = cb.greaterThanOrEqualTo(ageVar, 5).and(cb.lessThanOrEqualTo(ageVar, 18));

cb.selectCase().when(infantAge, "Infant").when(schoolAge, "Child").otherwise("Adult");

so this generates the equivalent of this JPQL

```
CASE WHEN (p.age < 5) THEN 'Infant' WHEN (p.age >= 5 AND p.age <= 18) THEN 'Child'
ELSE 'Adult'
```

Criteria API : Result as Tuple

You sometimes need to define a result for a query. You can define a result class just like with normal JPQL, but a special case is where you don't have a particular result class and want to use the built-in Jakarta Persistence standard `Tuple` class.

```
CriteriaQuery<Tuple> crit = cb.createTupleQuery();
```

Executing a Criteria query

Ok, so we've seen how to generate a Criteria query. So how can we execute it? This is simple; convert it into a standard Jakarta query, set any parameter values and execute it.

```
Query query = em.createQuery(crit);
List<Person> results = query.getResultList();
```

Criteria API : UPDATE query

So the previous examples concentrated on SELECT queries. Let's now do an UPDATE
which equates to

```
UPDATE Person p SET p.firstName = 'Freddie' WHERE p.firstName = 'Fred'
```

## Criteria API: DELETE query

So the previous examples concentrated on SELECT queries. Let’s now do a DELETE
which equates to

```
DELETE FROM Person p WHERE p.firstName = 'Fred'
```

## Static MetaModel

As we mentioned at the start of this section, there is a Static MetaModel allowing refactorability. In Jakarta Persistence the MetaModel is a *static metamodel* of generated classes that mirror the applications entities and have persistable fields marked as *public* and *static* so that they can be accessed when generating the queries. In the examples above you saw reference to a class with name with suffix ".\_". This is a (static) metamodel class. It is defined below.

The Jakarta Persistence spec contains the following description of the static metamodel.

*For every managed class in the persistence unit, a corresponding metamodel class is produced as follows:*

- For each managed class X in package p, a metamodel class X\_ in package p is created.
- The name of the metamodel class is derived from the name of the managed class by appending "\_" to the name of the managed class.
- The metamodel class X\_ must be annotated with the jakarta.persistence.StaticMetamodel annotation.
- If class X extends another class S, where S is the most derived managed class (i.e., entity or mapped superclass) extended by X, then class X\_ must extend class S\_, where S\_ is the metamodel class created for S.
- For every persistent non-collection-valued attribute y declared by class X, where the type of y is Y, the metamodel class must contain a declaration as follows:

```
public static volatile SingularAttribute<X, Y> y;
```

- For every persistent collection-valued attribute z declared by class X, where the element type of z is Z, the metamodel class must contain a declaration as follows:
  - if the collection type of z is java.util.Collection, then
    ```
    public static volatile CollectionAttribute<X, Z> z;
    ```
  - if the collection type of z is java.util.Set, then
    ```
    public static volatile SetAttribute<X, Z> z;
    ```
  - if the collection type of z is java.util.List, then
    ```
    public static volatile ListAttribute<X, Z> z;
    ```
• if the collection type of z is java.util.Map, then

```java
public static volatile MapAttribute<X, K, Z> z;
```

where K is the type of the key of the map in class X

Let's take an example, for the following class

```java
package mydomain.metamodel;

import java.util.*;
import jakarta.persistence.*;

@Entity
public class Person {
    @Id
    long id;

    String name;

    @OneToMany
    List<Address> addresses;
}
```

the static metamodel class (generated by datanucleus-jakarta-query.jar) will be

```java
package mydomain.metamodel;

import jakarta.persistence.metamodel.*;

@StaticMetamodel(Person.class)
public class Person_
{
    public static volatile SingularAttribute<Person, Long> id;
    public static volatile SingularAttribute<Person, String> name;
    public static volatile ListAttribute<Person, Address> addresses;
}
```

So how do we generate this metamodel definition for our query classes? DataNucleus provides an annotation processor in datanucleus-jakarta-query.jar that can be used when compiling your model classes to generate the static metamodel classes. What this does is when the compile is invoked, all classes that have persistence annotations will be passed to the annotation processor and a Java file generated for its metamodel. Then all classes (original + metamodel) are compiled.
Using Maven

To enable this in Maven you would need the above jar as well as `jakarta.persistence.jar` to be in the CLASSPATH at compile. This creates the "static metamodel" classes under `target/generated-sources/annotations/`. You can change this location using the configuration property `generatedSourcesDirectory` of the `maven-compiler-plugin`.

Using Eclipse

To enable this in Eclipse you would need to do the following

- Go to `Java Compiler` and make sure the compiler compliance level is 1.8 or above (needed for DN 5+ anyway)
- Go to `Java Compiler` → `Annotation Processing` and enable the project specific settings and enable annotation processing
- Go to `Java Compiler` → `Annotation Processing` → `Factory Path`, enable the project specific settings and then add the following jars to the list: `datanucleus-jakarta-query.jar`, `jakarta.persistence.jar`

This creates the "static metamodel" classes under `target/generated-sources/annotations/`. You can change this location on the `Java Compiler` → `Annotation Processing` page.
Native Queries

The Jakarta Persistence specification defines its interpretation of native queries, for selecting objects from the datastore. To provide a simple example for RDBMS (i.e using SQL), this is what you would do

```java
Query q = em.createNativeQuery("SELECT p.id, o.firstName, o.lastName FROM Person p,
Job j WHERE (p.job = j.id) AND j.name = 'Cleaner'");
List results = (List)q.getResultsList();
```

This finds all "Person" objects that do the job of "Cleaner". The syntax chosen has to be runnable on the RDBMS that you are using (and since SQL is anything but "standard" you will likely have to change your query when moving to another datastore).

Input Parameters

In queries it is convenient to pass in parameters so we don't have to define the same query for different values. Here's an example

```java
// Numbered Parameters :
Query q = em.createQuery("SELECT p.id FROM Person p WHERE p.lastName = ?1 AND
p.firstName = ?2");
q.setParameter(1, theSurname).setParameter(2, theForename);
```

So we have parameters that are prefixed by ? (question mark) and are numbered starting at 1. We then use the numbered position when calling Query.setParameter(). This is known as numbered parameters. With Jakarta native queries we can’t use named parameters officially.

DataNucleus also actually supports use of named parameters where you assign names just like in JPQL. This is not defined by the Jakarta Persistence specification so dont expect other Jakarta implementations to support it. Let’s take the previous example and rewrite it using named parameters, like this

```java
// Named Parameters :
Query q = em.createQuery("SELECT p.id FROM Person p WHERE p.lastName = :firstParam AND
p.firstName = :otherParam");
q.setParameter("firstParam", theSurname).setParameter("otherParam", theForename);
```

Range of Results

With SQL you can select the range of results to be returned. For example if you have a web page and you are paginating the results of some search, you may want to get the results from a query in blocks of 20 say, with results 0 to 19 on the first page, then 20 to 39, etc. You can facilitate this as follows
Query q = em.createNativeQuery("SELECT p.id FROM Person p WHERE p.age > 20");
q.setFirstResult(0).setMaxResults(20);

So with this query we get results 0 to 19 inclusive.

**SQL Syntax Checks**

When a native query is a SELECT, and is returning instances of an Entity, then it is required to return the columns for the PK, version and discriminator (if applicable). DataNucleus provides some checks that can be performed to ensure that these are selected. You can turn this checking off by setting the persistence property `datanucleus.query.sql.syntaxChecks` to `false`. Similarly you can turn them off on a query-by-query basis by setting the query hint `datanucleus.query.sql.syntaxChecks` to `false`.

**Query Execution**

There are two ways to execute a native query. When you know it will return 0 or 1 results you call

```
Object result = query.getSingleResult();
```

If however you know that the query will return multiple results, or you just don’t know then you would call

```
List results = query.getResultList();
```

**SQL Result Definition**

By default, if you simply execute a native query and don’t specify the result mapping, then when you execute `getResultList()` each row of the results will be an Object array. You can however define how the results are mapped to some result class for example. Let’s give some examples of what you can do. If we have the following entities
The first thing to do is to select both LOGIN and LOGINACCOUNT columns in a single call, and return instances of the 2 entities. So we define the following in the LoginAccount class:

```java
@Entity
@Table(name="LOGINACCOUNT")
public class LoginAccount {
    @Id
    private long id;

    private String firstName;
    private String lastName;

    @OneToOne(cascade={CascadeType.MERGE, CascadeType.PERSIST}, orphanRemoval=true)
    @JoinColumn(name="LOGIN_ID")
    private Login login;

    public LoginAccount(long id, String firstName, String lastName) {
        ...}
}
```

The @SqlResultSetMappings annotation is used to define the mapping of the query result set to the entities. In this case, we define two entity results:

```java
@SqlResultSetMappings(
    @SqlResultSetMapping(name="LOGIN_PLUS_ACCOUNT", entities={
        @EntityResult(entityClass=LoginAccount.class), @EntityResult(entityClass=Login.class)
    }))
```

and we now execute the native query as
Next thing to try is the same as above, returning 2 entities for a row, but here we explicitly define the mapping of SQL column to the constructor parameter.

```java
@SqlResultSetMapping(name="AN_LOGIN_PLUS_ACCOUNT_ALIAS", entities={
    @EntityResult(entityClass=LoginAccount.class, fields={
        @FieldResult(name="id", column="THISID"),
        @FieldResult(name="firstName", column="FN")
    }),
    @EntityResult(entityClass=Login.class, fields={
        @FieldResult(name="id", column="IDLOGIN"),
        @FieldResult(name="userName", column="UN")
    })
})
```

and we now execute the native query as

```java
List<Object[]> result = em.createNativeQuery("SELECT P.ID AS THISID, P.FIRSTNAME AS FN, P.LASTNAME, P.LOGIN_ID, 
    L.ID AS IDLOGIN, L.USERNAME AS USER, L.PASSWORD FROM JKA_AN_LOGINACCOUNT P, JKA_AN_LOGIN L", "AN_LOGIN_PLUS_ACCOUNT_ALIAS").getResultList();
Iterator iter = result.iterator();
while (iter.hasNext())
{
    Object[] row = iter.next();
    LoginAccount acct = (LoginAccount)obj[0];
    Login login = (Login)obj[1];
    ... 
}
```

For our final example we will return each row as a non-entity class, defining how the columns map to the constructor for the result class.

```java
@SqlResultSetMapping(name="AN_LOGIN_PLUS_ACCOUNT_CONSTRUCTOR", classes={
    @ConstructorResult(targetClass=LoginAccountComplete.class,
        columns={
            @ColumnResult(name="FN"), @ColumnResult(name="LN"),
            @ColumnResult(name="USER"), @ColumnResult(name="PWD")
        })
})
```
with non-entity result class defined as

```java
public class LoginAccountComplete {
    String firstName;
    String lastName;
    String userName;
    String password;

    public LoginAccountComplete(String firstName, String lastName, String userName, String password) {
        ...
    }

    ...
}
```

and we execute the query like this

```java
List result = em.createNativeQuery("SELECT P.FIRSTNAME AS FN, P.LASTNAME AS LN, L.USERNAME AS USER, L.PASSWORD AS PWD FROM " + "JKA_AN_LOGINACCOUNT P, JKA_AN_LOGIN L","AN_LOGIN_PLUS_ACCOUNT_CONSTRUCTOR"").getResultList();
Iterator iter = result.iterator();
while (iter.hasNext()) {
    LoginAccountComplete acctCmp = (LoginAccountComplete)iter.next();
    ...
}
```

## Named Native Query

With the Jakarta Persistence API you can either define a query at runtime, or define it in the MetaData/annotations for a class and refer to it at runtime using a symbolic name. This second option means that the method of invoking the query at runtime is much simplified. To demonstrate the process, lets say we have a class called Product (something to sell in a store). We define the Jakarta Meta-Data for the class in the normal way, but we also have some query that we know we will require, so we define the following in the Meta-Data.

```xml
<entity class="Product">
    ...
    <named-native-query name="PriceBelowValue"><![CDATA[
        SELECT NAME FROM PRODUCT WHERE PRICE < ?1
    ]]></named-native-query>
</entity>
```
or using annotations

```java
@Entity
@NamedNativeQuery(name="PriceBelowValue", query="SELECT NAME FROM PRODUCT WHERE PRICE < ?1")
public class Product {...}
```

So here we have a native query that will return the names of all Products that have a price less than a specified value. This leaves us the flexibility to specify the value at runtime. So here we run our named native query, asking for the names of all Products with price below 20 euros.

```java
Query query = em.createNamedQuery("PriceBelowValue");
List results = query.setParameter(1, new Double(20.0)).getResultList();
```

**Cassandra Native (CQL) Queries**

*If you choose to use Cassandra CQL Queries then these are not portable to any other datastore. Use JPQL for portability*

Cassandra provides the CQL query language. To take a simple example using it with the Jakarta Persistence API and a Cassandra datastore

```java
// Find all employees
Query q = em.createNativeQuery("SELECT * FROM schema1.Employee", Employee.class);
List<Employee> results = (List)q.getResultList();
```

Note that the last argument to `createNativeQuery` is optional and you would get `List<Object[]>` returned otherwise.
Stored Procedures

The Jakarta Persistence specification supports calling stored procedures through its API. It allows some flexibility in the type of stored procedure being used, supporting IN/OUT/INOUT parameters as well as result sets being returned. Obviously if a particular RDBMS does not support stored procedures then this functionality will not apply.

You start off by creating a stored procedure query, like this, referencing the stored procedure name in the datastore.

```java
StoredProcedureQuery spq = em.createStoredProcedureQuery("PERSON_SP_1");
```

You should familiarise yourself with the StoredProcedureQuery API.

If we have any parameters in this stored procedure we need to register them, for example

```java
spq.registerStoredProcedureParameter("PARAM1", String.class, ParameterMode.IN);
spq.registerStoredProcedureParameter("PARAM2", Integer.class, ParameterMode.OUT);
```

If you have any result class, or result set mapping then you can specify those in the `createStoredProcedureQuery` call. Now we are ready to execute the query and access the results.

**Simple execution, returning a result set**

A common form of stored procedure will simply return a single result set. You execute such a procedure as follows

```java
List results = spq.getResultList();
```

or if expecting a single result, then

```java
Object result = spq.getSingleResult();
```

**Simple execution, returning output parameters**

A common form of stored procedure will simply return output parameter(s). You execute such a procedure as follows

```java
spq.execute();
Object paramVal = spq.getOutputParameterValue("PARAM2");
```
Generalised execution, for multiple result sets

A more complicated, yet general, form of execution of the stored procedure is as follows

```java
boolean isResultSet = spq.execute(); // returns true when we have a result set from the proc
List results1 = spq resultList(); // get the first result set
if (spq.hasMoreResults())
{
    List results2 = spq.getResultList(); // get the second result set
}
```

So the user can get hold of multiple result sets returned by their stored procedure.

Named Stored Procedure Queries

Just as with normal queries, you can also register a stored procedure query at development time and then access it via name from the EntityManager. So we define one like this (not important on which class it is defined)

```java
@NamedStoredProcedureQuery(name="myTestProc", procedureName="MY_TEST_SP_1",
        parameters={@StoredProcedureParameter(name="PARAM1", type=String.class, mode =ParameterMode.IN})

@Entity
public class MyClass {...}
```

and then create the query from the EntityManager

```java
StoredProcedureQuery spq = em.createNamedStoredProcedureQuery("myTestProc");
```
Query Cache

Jakarta Persistence doesn’t currently define a mechanism for caching of queries. DataNucleus provides 3 levels of caching:

- **Generic Compilation**: when a query is compiled it is initially compiled *generically* into expression trees. This generic compilation is independent of the datastore in use, so can be used for other datastores. This can be cached.

- **Datastore Compilation**: after a query is compiled into expression trees (above) it is then converted into the native language of the datastore in use. For example with RDBMS, it is converted into SQL. This can be cached.

- **Results**: when a query is run and returns objects of the candidate type, you can cache the identities of the result objects.

**Generic Query Compilation Cache**

This cache is by default set to *soft*, meaning that the generic query compilation is cached using soft references. This is set using the persistence property `datanucleus.cache.queryCompilation.type`. You can also set it to *strong* meaning that strong references are used, or *weak* meaning that weak references are used.

You can turn caching on/off (default = on) on a query-by-query basis by specifying the query extension `datanucleus.query.compilation.cached` as true/false.

**Datastore Query Compilation Cache**

This cache is by default set to *soft*, meaning that the datastore query compilation is cached using soft references. This is set using the persistence property `datanucleus.cache.queryCompilationDatastore.type`. You can also set it to *strong* meaning that strong references are used, or *weak* meaning that weak references are used.

You can turn caching on/off (default = on) on a query-by-query basis by specifying the query extension `datanucleus.query.compilation.cached` as true/false. As a finer degree of control, where cached results are used, you can omit the validation of object existence in the datastore by setting the query extension `datanucleus.query.resultCache.validateObjects`. 
Query Results Cache

This cache is by default set to soft, meaning that the datastore query results are cached using soft references. This is set using the persistence property `datanucleus.cache.queryResults.type`. You can also set it to strong meaning that strong references are used, or weak meaning that weak references are used.

You can specify persistence property `datanucleus.cache.queryResults.cacheName` to define the name of the cache used for the query results cache.

You can specify persistence property `datanucleus.cache.queryResults.expireMillis` to specify the expiry of caching of results, for caches that support it.

You can specify persistence property `datanucleus.cache.queryResults.maxSize` to define the maximum number of queries that have their results cached, for caches that support it.

You can turn caching on/off (default = off) on a query-by-query basis by specifying the query extension `datanucleus.query.results.cached` as true/false.

Obviously with a cache of query results, you don't necessarily want to retain this cached over a long period. In this situation you can evict results from the cache like this.

```java
import org.datanucleus.api.jakarta.JakartaQueryCache;
import org.datanucleus.api.jakarta.JakartaEntityManagerFactory;

... 
JakartaQueryCache cache = ((JakartaEntityManagerFactory)emf).getQueryCache();

cache.evict(query);
```

which evicts the results of the specific query. The JakartaQueryCache has more options available should you need them.
